

## Container Handler

Used Container Handler Oklahoma - Container handlers, also known as cargo ships and container ships transport their load in a large intermodal container. Containerization is the shipping method that utilizes commercial freight transport to carry seagoing cargo in non-bulk sizes. The capacity of these specialty ships is equal to twenty-foot loads. Most loads are a mix of 20' and 40' containers. Container ships are responsible for transporting roughly ninety percent of non-bulk items across the globe. These ships are one of the main oil tanker rivals due to their size as one of the biggest sea-worthy ships. Dry cargo falls into two main categories: bulk cargo and break-bulk cargo. Coal and grain are considered to be bulk cargo items. They are typically transported in their raw form within the hull of the ship, free from packages in immense volume. Break-bulk cargo typically is made up of manufactured items that are shipped in packaging. Before containerization was invented in the 50s, break-bulk items were loaded, secured and unlashd one item at a time. When the cargo was grouped into containers, there were approximately 1000-3000 cubic feet of cargo that can be simultaneously moved after each unit has been standardized and secured. Overall efficiency has largely increased with break-bulk cargo shipping. Thanks to these new systems, shipping time has been reduced by eighty-four percent and costs have come down by roughly thirty-five percent. In 2001, over ninety percent of non-bulk materials were recorded as being transported in containers. In the 1940s, the first container ships were made from tankers that underwent conversion after World War II. Cargo ships do not use individual dividers, holds or hatches that are a part of traditional container ships. Essentially the container ship's hull is similar to a huge warehouse that uses vertical guide rails to divide it into cells. These cells have been engineered to hold the cargo in containers. Most cargo ships are designed from steel but additional materials such as plywood, fiberglass and wood are used. Designed to be completely transferred to and from trains, semi-trailers, trucks, coastal carriers and more, there is a variety of container types that are categorized by their function and size. Even though the shipping industry has been transformed by containerization, it took some time to streamline the process. Railway companies, ports and shippers were initially concerned about the extensive costs associated with building the railway infrastructure and ports required to accommodate container ships, along with moving the containers via road and rail. There was skepticism regarding potential dock and port worker job loss when containerization was announced for fear that numerous manual jobs would disappear. There was a decade of legal battles prior to the container ships starting international service. By 1966, after the first container liner service began from Rotterdam, Netherlands to the USA, cargo shipping was transformed. Initially, it took days to unload and load traditional cargo vessels. Container ships have transformed timelines by only requiring a few hours for loading and unloading. Shipping times have been shortened in between ports extensively along with labor finances. It only takes 3 weeks to have materials delivered from Europe to India as opposed to the months it used to require. Overall, there is less damaged cargo thanks to less physical handling and reduced cargo shifting due to properly securing loads. Before shipping, containers are closed and only opened after they arrive at their new location to prevent theft and damage. There have been less shipping expenses and shipping time thanks to container ships which has increased international trade. Sealed factory containers now carry cargo that used to arrive in barrels, cartons, crates, bags and bales. A product code on the contents is traced with the help of computers and scanning equipment. Technology has made this tracking system accurate and exact to enable a two week voyage to be timed for arrival within an accuracy rate of under fifteen minutes. This has helped with guaranteed delivery and manufacturing times. Sealed containers of raw materials arrive in under an hour to be used in manufacturing facilities, resulting in less inventory costs and higher accuracy. Boxes are provided by shipping companies to the exporters to facilitate loading merchandise. Materials are delivered by rail or docks or a combination of both and then loaded into container handlers. Containerization has streamlined the process of loading by reducing the number of workers and hours it takes to fit cargo into

their holds. The shipping industry today relies on cranes either installed on the ship or on the pier to situate containers on board. More containers can be loaded onto the deck after the hull is loaded. An efficient design has been a huge priority for shipping containers. Containers may be carried on break-bulk ships. However, cargo holds that have been dedicated to container ships have been carefully built to speed up the loading and unloading process and designed to keep containers secure while traveling the ocean. The specialized hatch design allows openings from the main deck to access the cargo holds. These openings flow along the whole cargo hold area and are surrounded by the hatch coaming which is a raised steel structure. The hatch coamings have hatch covers located on them. Until the 1950s, wooden boards and tarps were responsible for securing the hatches and holding down the battens. These days, hatch covers often consist of solid metal plates that are lifted on and off the ship with cranes. Additional hatch models use hydraulic rams and articulated mechanisms for closing and opening. Another important cargo ship design feature is cell guides. The cell guides are vertical pieces constructed of strong metal that is attached to the cargo hold within the ship. These guide the containers into certain locations and offer travel support on the high seas. The container ship design relies on cell guides so much that organizations as the United Nations Conference on Trade and Development use them to differentiate between regular break-bulk cargo ships and container ships. There are three dimensions used in cargo plans to determine the position of the container on board the ship. The initial coordinate starts at the beginning of the ship and increases aft. The second coordinate is the tier. The first tier begins in the lower portion of the cargo holds with the second tier found on top of the first tier and continuing in that fashion. The row is the third coordinate. Rows found on the port side of the ship exhibit even numbers and those located on the starboard side are given odd numbers. The cargo situated near the centerline showcases lower numbers and as the cargo increases further from the center, the numbers get higher. Container handlers can handle forty-five, or forty or twenty-foot containers. The biggest sizes only fit above the deck. The forty-foot containers comprise most of the load or roughly 90% of container shipping. Container shipping is responsible for moving approximately ninety percent of the freight across the globe, while roughly eighty percent of global freight moves with 40 foot containers.
